

The main difference is that **HTML/CSS is static**, while **React is dynamic and interactive**.

Think of building a house: **HTML** is the wooden framing, **CSS** is the paint and interior design, and **React** is the smart automation system that lets you change the wallpaper or move furniture instantly with the press of a button.

Here is a direct breakdown of how they compare:

Feature	Standard HTML / CSS	React
What it is	The core languages of the web. HTML structures the page; CSS styles it.	A JavaScript framework (library) built on top of HTML, CSS, and JavaScript.
How it updates	To change information, the user usually has to reload the entire browser webpage .	Updates the page instantly in real-time without reloading , making it feel like a mobile app.
Reusability	Low . If you have 10 job listings, you have to copy and paste the same HTML code 10 times.	High . You write a single JobCard template once and pass different data into it.
Code Structure	HTML and CSS are typically written in separate files (index.html and styles.css).	Combines layout (HTML) and logic (JavaScript) together into self-contained Components .

Visual Code Example: Creating a Profile Button

In Traditional HTML & CSS:

You write static layout blocks. To make it interactive, you would have to write completely separate JavaScript code files to find the element and manually change it.

```
<!-- HTML File -->
<button class="upload-btn">Upload Resume</button>

<!-- CSS File -->
<style>
```

```
.upload-btn { background-color: blue; color: white; padding: 10px; }  
</style>
```

In React:

You write UI and state logic together. The button changes appearance or state automatically depending on variables (like whether a file is loading or finished).

```
// React Component  
export default function UploadButton() {  
  const [isUploaded, setIsUploaded] = useState(false);  
  
  return (  
    <button className={isUploaded ? "bg-green-500" :  
"bg-blue-500"}>  
      {isUploaded ? "Done!" : "Upload Resume"}  
    </button>  
  );  
}
```

Are you planning to build the CareerConnect frontend using **React**, or are you sticking with traditional **HTML/CSS/JavaScript** files? Let me know so I can tailor future code snippets to your setup!
